#### 3.1 Brute force algorithms [Sections 3.1 and 3.2]

Our first algorithm design technique is **brute force**. Brute force is a straightforward approach to solve a problem in a very easy, yet (usually) inefficient way. It is a Just-Do-It approach. To solve a problem using the brute force technique, you just need to use facts derived from the problem statement without making an effort to make the algorithm smart.

Example:

Consider the problem of telling whether a positive integer is a prime number or not.

---

**Algorithm 1:** Telling whether a positive integer is prime or not.

---

```
Algorithm Prime( $n$ )
  if  $n \leq 1$  then
    return False;
  end
   $i := n - 1$ ;
  while  $i > 1$  AND  $n \bmod i > 0$  do
     $i := i - 1$ ;
  end
  if  $i > 1$  then
    return False;
  else
    return True;
  end
```

---

---

<sup>1</sup>This is a summary of the material we cover from the textbook: *Introduction to the Design & Analysis of Algorithms*, A. Levitin, Second Edition, Pearson Addison-Wesley, 2006.

### 3. Brute Force Algorithms

---

Example: Selection sort

---

**Algorithm 2:** Selection Sort.

---

```
Algorithm SelectionSort( $A[0..n-1]$ )  
  for  $i:=0..n-2$  do  
     $min:=i$ ;  
    for  $j:=i+1..n-1$  do  
      if  $A[j] < A[min]$  then  
         $min:=j$ ;  
      end  
    end  
    swap  $A[i]$  and  $A[min]$ ;  
  end
```

---

The major operation count is  $\sum_{i=0}^{n-2} \sum_{j=i+1}^{n-1} 1 = \sum_{i=0}^{n-2} (n-1-i) = \frac{n(n-1)}{2} \in \Theta(n^2)$ .

Example: Bubble sort

---

**Algorithm 3:** Bubble Sort.

---

```
Algorithm BubleSort( $A[0..n-1]$ )  
  for  $i:=0..n-2$  do  
    for  $j:=0..n-2-i$  do  
      if  $A[j+1] < A[j]$  then  
        swap  $A[j]$  and  $A[j+1]$ ;  
      end  
    end  
  end
```

---

The major operation count is  $\sum_{i=0}^{n-2} \sum_{j=0}^{n-2-i} 1 = \sum_{i=0}^{n-2} [(n-2-i) + 1] = \frac{n(n-1)}{2} \in \Theta(n^2)$ .

### 3. Brute Force Algorithms

---

Example:

Consider the string match problem in which you are given a string called text and another string called the pattern, and you are asked to tell whether a substring of the text matches the pattern. The algorithm is supposed to return the index of the leftmost character that starts a matching substring if such a matching substring exists and -1 otherwise. The major

---

**Algorithm 4:** Brute force string matching.

---

```
Algorithm StringMatching( $T[0..n-1], P[0..m-1]$ )  
  for  $i:=0..n-m$  do  
     $j:=0$ ;  
    while  $j < m$  AND  $P[j] == T[i+j]$  do  
       $j:=j+1$ ;  
    end  
    if  $j == m$  then  
      return  $i$ ;  
    end  
  end  
  return -1;
```

---

operation count is  $(n - m + 1)m \in \Theta(nm)$ .

### 3.2 Exhaustive search [Sections 3.4]

Exhaustive search is a brute force algorithm design technique in which all elements in the search space are generated, and then all elements are checked to find a particular element that represents the answer. Exhaustive search is composed of the following steps:

1. Generate all elements in the search space.
2. Exclude any invalid element.
3. Find a desired element representing the right (best) answer.

Question: Let's say that we have a set  $A = \{E_0, E_1, \dots, E_{n-1}\}$ . How can you find all subsets of  $A$ ?

### 3. Brute Force Algorithms

---

Answer: We can have  $2^n$  subsets, each of which can be represented by an integer between 0 and  $2^n - 1$ . Let  $B(s)$  be the binary representation of an integer that corresponds to a subset  $s$ .  $B(s)$  has  $n$  binary bits numbered from 0 to  $n - 1$ , and the  $i^{\text{th}}$  binary bit corresponds to  $E_i$ .

The  $i^{\text{th}}$  bit in  $B(s)$  is set to 1 if and only if  $E_i \in s$ ,  $0 \leq i \leq n - 1$ .

Example:

$A = \{Ali, Mohammed, Ahmed\}$

$s = \{Ali, Ahmed\}$

$B(s) = 101$

Question: Given an integer  $t$ , how to tell whether the  $i^{\text{th}}$  bit of the binary representation of  $t$  is 1 or 0?

Answer: Left as an exercise!

Example:

**Knapsack problem:** You have  $n$  items and each item  $i$  has a weight  $W[i]$  and a value  $V[i]$ . You have a knapsack of capacity  $C$ . You want to find the most valuable subset of items that fit into the knapsack.

---

**Algorithm 5:** Finding the  $b^{\text{th}}$  bit of the binary representation of an integer  $t$ .

---

**Algorithm BinaryBit**(int  $t$ , int  $b$ )

This algorithm returns the value of the  $b^{\text{th}}$  bit in the binary representation of an integer  $t$ .

---

This algorithm runs in  $O(n \cdot 2^n)$  time.

### 3. Brute Force Algorithms

---

---

**Algorithm 6:** Brute force knapsack algorithm.

---

**Algorithm Knapsack**( $W[0..n-1], V[0..n-1], C$ )  
   $MaxValue = 0$ ;  
   $MaxSubset = 0$ ;  
  **for**  $i:=1..2^n-1$  **do**  
     $Value:=0$ ;  
     $Weight := 0$ ;  
    **for**  $j:=0..n-1$  **do**  
      **if**  $BinaryBit(i,j)==1$  **then**  
         $Value := Value + V[j]$ ;  
         $Weight := Weight + W[j]$ ;  
      **end**  
    **end**  
    **if**  $Weight \leq C$  **AND**  $Value > MaxValue$  **then**  
       $MaxValue = Value$ ;  
       $MaxSubset = i$ ;  
    **end**  
  **end**  
  **return**  $MaxSubset$ ;

---
